    abstract "Endothelial cell proliferation and differentiation into blood
capillaries (i.e., angiogenesis) are essential for growth and development,
wound healing, osetogenesis, etc. But abnormal angiogenesis during tumor
progression could lead to serious consequences. Angiogenesis is a complex
biochemical process, and is often difficult to study the molecular mechanism
in vivo due to interference by multitude of factors. Here, I present a
non-transformed capillary endothelial cell line as a model which has been
extensively characterized morphologically and biochemically to study the
fundamentals of the angiogenic process. Studies completed in our laboratory
also evidenced that expression of Glc3Man9GlcNAc2-PP-Dol is intricately
connected with the balance between the cellular proliferation and apoptosis
during angiogenesis." ,
